Overview of Mitochondrial Diagnosis

- Basic Mito Facts and Background, including what mitochondria do
- Types of problems that can be caused by Mito dysfunction
- Genetics, in brief
- Mito Diseases - what are they and how are they classified (OXPHOS, Leigh's, MELAS, etc.)
- Inherent problems in diagnosis/diagnostic approaches of both OXPHOS and mtDNA disease - Heteroplasmy
- Testing, in brief, including advantages and limitations of new nDNA gene sequencing
- Clues to the diagnosis of mitochondrial disease for clinicians (and families)
- How does one arrive at a diagnosis of Mito disease? Combination of clinical testing, biochemical testing, personal and family history, and symptoms/clinical presentation
- Why are more invasive tests (i.e. muscle biopsy) sometimes necessary?
- How is the field of mitochondrial medicine changing? Are there new types of mitochondrial disease? What may the future look like for this field and for patients/families?

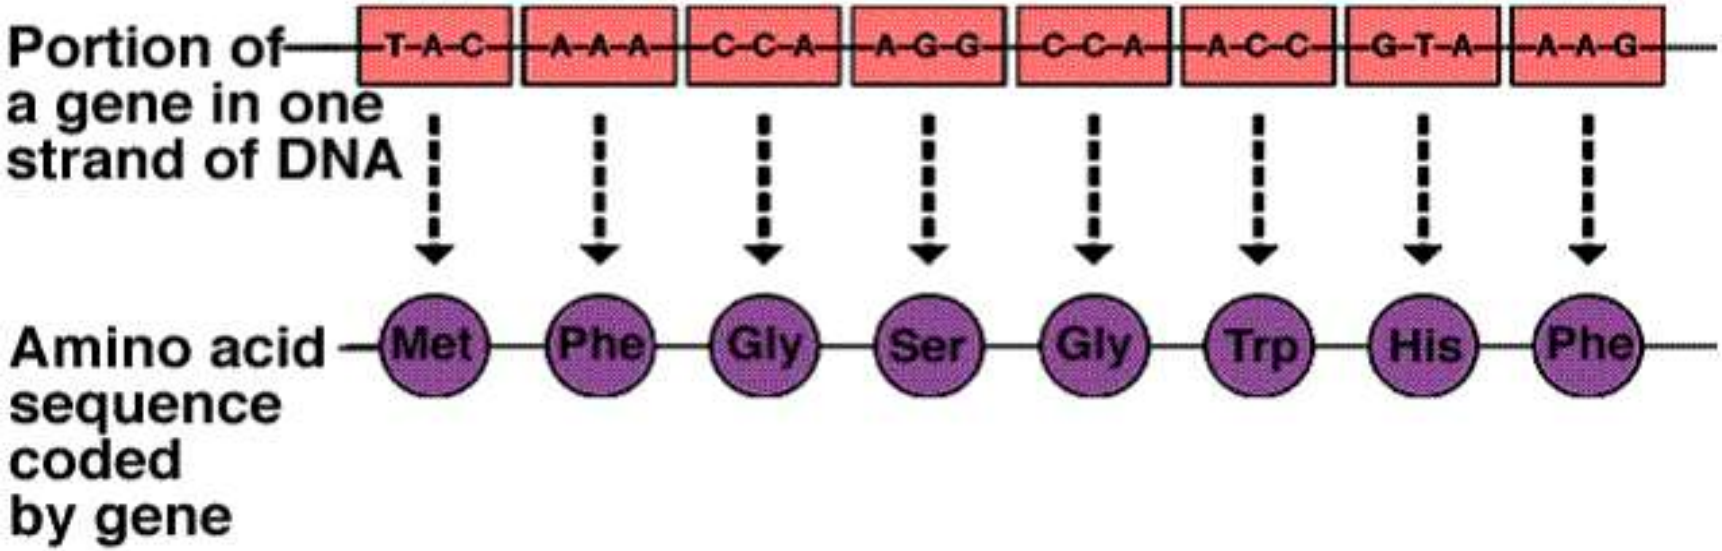
Triplet Codes



Basic Mito Facts

- Prokaryote (Bacterial) origin of mitochondria & mtDNA – symbiotic relationship
- 1500 nuclear mitochondrial genes
- 2-10 mtDNA molecules per mitochondrion
- 100 – 10,000 mitochondria per nucleated cell
- mtDNA is maternally inherited

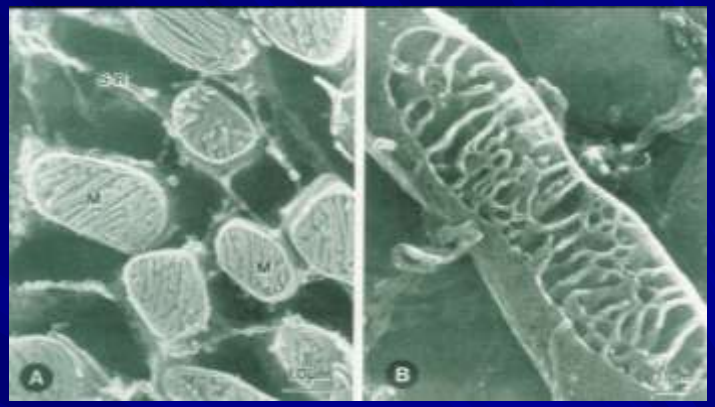
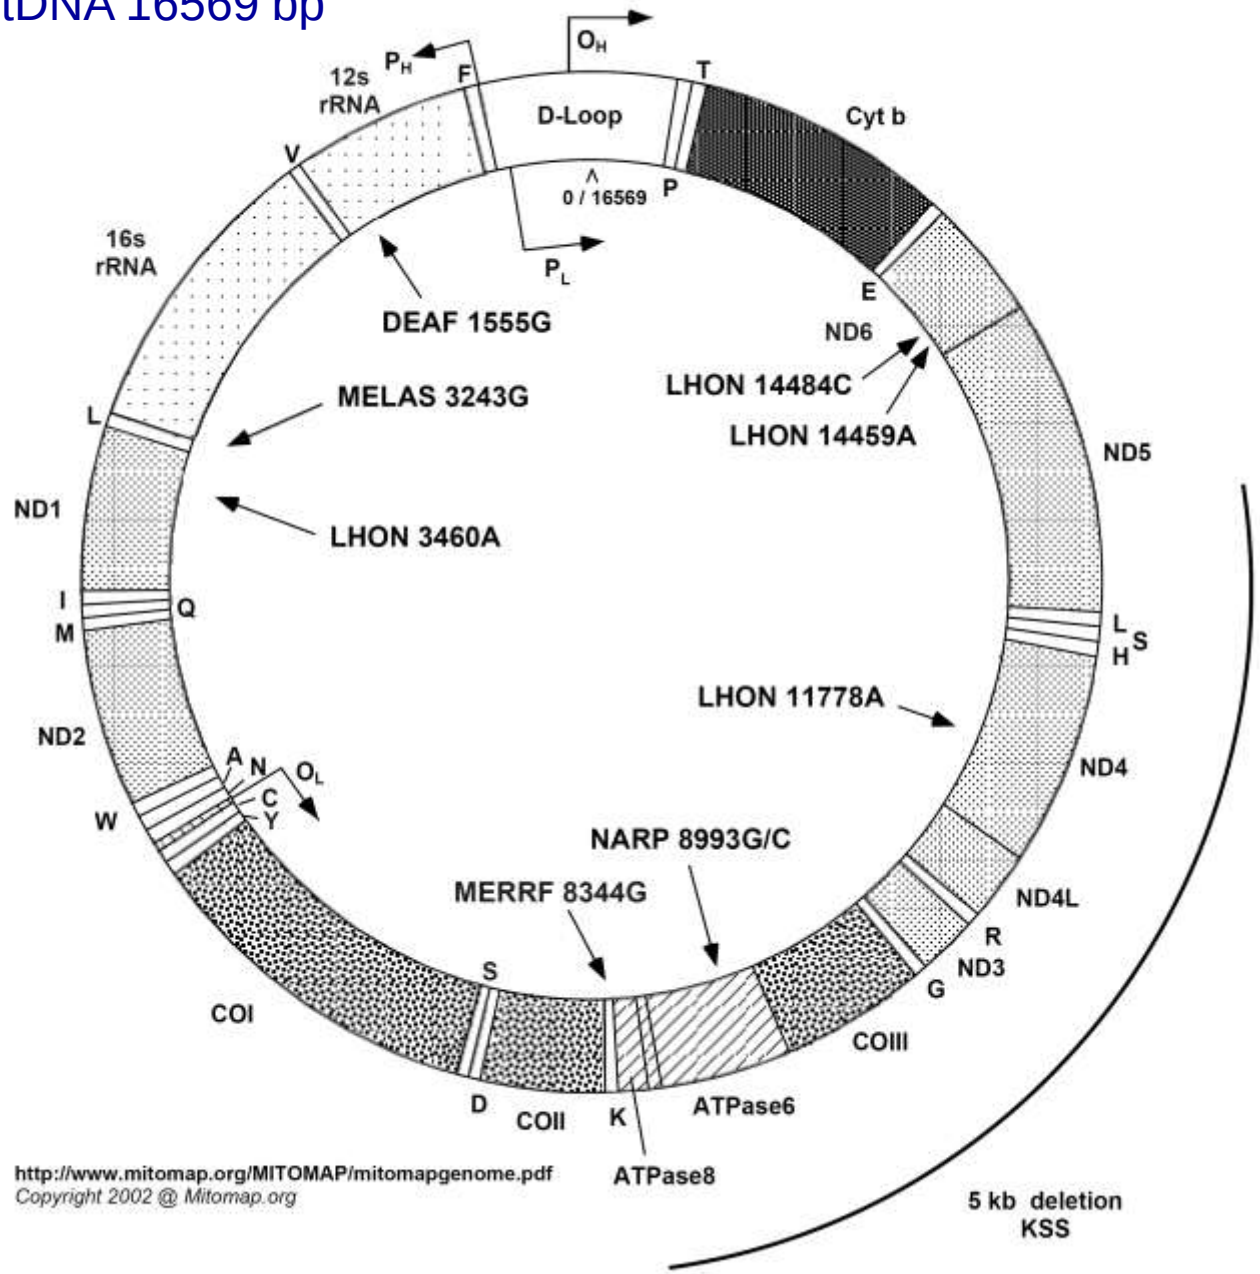
Major Mitochondrial Functions

- Make ATP for cellular energy – oxidative phosphorylation
- Metabolize
  - fats
  - carbohydrates
  - amino acids



- Interconvert carbohydrates, fats and amino acids
- Synthesize some proteins
- Reproduce themselves (replicate), fusion/fission
- Participate in apoptosis
- Make free radicals
- Innate Immunity

Human mtDNA 16569 bp



Oxphos Disease

A disease of energy metabolism resulting in impairment of oxidative phosphorylation

Nuclear Gene Defects (80% of Child disease)

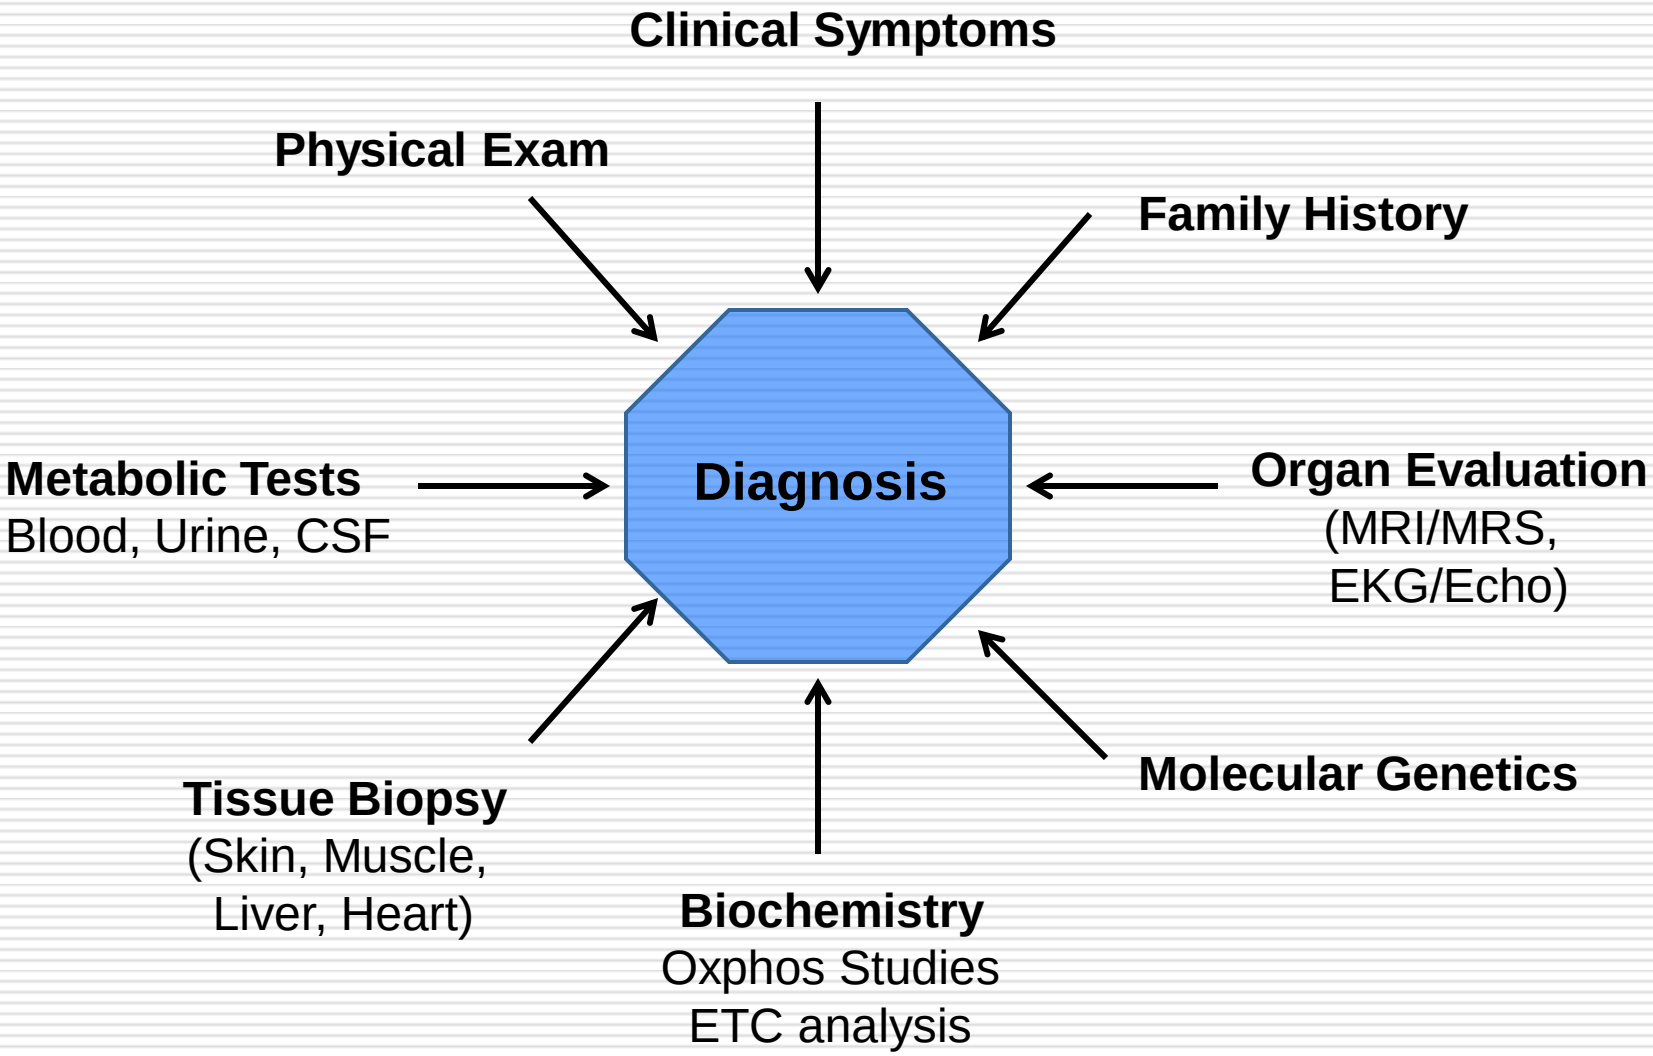
DIAGNOSTIC EVALUATION OF MITOCHONDRIAL DISEASE

The major challenge to properly establishing mitochondrial dysfunction as the cause of a patient's presentation is the absence of a definitive biomarker that characterizes mitochondrial disease in all patients. Thus, the diagnostic evaluation is necessarily multitiered and broad-based, with a focus on integrating information from many avenues: the complete medical and family history, clinical findings that may be suggestive of mitochondrial disease (see Tables 1 and 2), biochemical laboratory abnormalities such as lactic acidosis (which, as discussed above, is neither sensitive nor specific as a single biomarker for many mitochondrial disorders), tissue-biopsy evidence of abnormal electron-transport chain enzyme activity or impaired respiratory capacity, and, if possible, the identification of a pathogenic mtDNA or nDNA mutation.

Diagnosis of Mitochondrial Disease



Metabolic & Other Tests
Blood, Urine & CSF

- CPK
- Lactate and Pyruvate
- Ammonia
- Plasma Amino Acids
- Plasma Acyl-carnitine profile
- Plasma Carnitine
- Urine Organic Acids
- DNA Studies

Available Mito Tests

Test	Tissue
Histology/EM	Muscle, Liver, Heart
Carnitine, CoQ	
Nuclear DNA	Blood, All Tissues
mtDNA	All Tissues, Muscle Best
Electron Transport Assays	Muscle Fresh/Frozen, Fibroblasts, Liver, Heart
Polarographic Assay	Fresh muscle, Liver, Heart or Mitochondria
Enzyme Assay	All Tissues, Mitochondria, Fibroblasts
Protein Immunoassay	Mitochondria (Blue Native)
Immunocytochemistry	Tissue (Clear Native)
Immunohistochemistry	Fibroblasts/ Muscle Tissue

Tissue Diagnosis

- Available Tissues
  - Blood
  - Saliva (Buccal Epithelial Cells)
  - Urine Sediment
  - Muscle
  - Skin Fibroblasts
  - Other Tissues
    - Liver
    - Heart

Summary

- Tissue sampling for mitochondrial disease is dictated by the tests required. Nuclear DNA testing requires only blood
- Blood, saliva and urine for mtDNA testing are all feasible but heteroplasmy presents a problem
- Muscle biopsy remains the 'Gold Standard' for electron transport chain assay and for mtDNA testing
- Fresh muscle offers the opportunity to perform functional polarography and to isolate mitochondria for electron transport and protein study

Abstract

Mitochondrial disease confirmation and establishment of a specific molecular diagnosis requires extensive clinical and laboratory evaluation. Dual genome origins of mitochondrial disease, multi-organ system manifestations, and an ever increasing spectrum of recognized phenotypes represent the main diagnostic challenges. To overcome these obstacles, compiling information from a variety of diagnostic laboratory modalities can often provide sufficient evidence to establish an etiology. These include blood and tissue histochemical and analyte measurements, neuroimaging, provocative testing, enzymatic assays of tissue samples and cultured cells, as well as DNA analysis. As interpretation of results from these multifaceted investigations can become quite complex, the Diagnostic Committee of the Mitochondrial Medicine Society developed this review to provide an overview of currently available and emerging methodologies for the diagnosis of primary mitochondrial disease, with a focus on disorders characterized by impairment of oxidative phosphorylation. The aim of this work is to facilitate the diagnosis of mitochondrial disease by geneticists, neurologists, and other metabolic specialists who face the challenge of evaluating patients of all ages with suspected mitochondrial disease.

ARTICLE

Pathogenic Mitochondrial DNA Mutations Are Common in the General Population

Hannah R. Elliott,[1] David C. Samuels,[2] James A. Eden,[3] Caroline L. Relton,[3] and Patrick F. Chinnery[1,3,*]

Mitochondrial DNA (mtDNA) mutations are a major cause of genetic disease, but their prevalence in the general population is not known. We determined the frequency of ten mitochondrial point mutations in 3168 neonatal-cord-blood samples from sequential live births, analyzing matched maternal-blood samples to estimate the de novo mutation rate. mtDNA mutations were detected in 15 offspring (0.54%, 95% CI = 0.30–0.89%). Of these live births, 0.00107% (95% CI = 0.00087–0.0127) harbored a mutation not detected in the mother's blood, providing an estimate of the de novo mutation rate. The most common mutation was m.3243A→G. m.14484T→C was only found on sub-branches of mtDNA haplogroup J. In conclusion, at least one in 200 healthy humans harbors a pathogenic mtDNA mutation that potentially causes disease in the offspring of female carriers. The exclusive detection of m.14484T→C on haplogroup J implicates the background mtDNA haplotype in mutagenesis. These findings emphasize the importance of developing new approaches to prevent transmission.

The American Journal of Human Genetics 83, 254–260, August 8, 2008

Screened for just 10 (5%) of >200 known pathogenic mtDNA mutations.

Prevalence of Mitochondrial DNA Disease in Adults

Andrew M. Schaefer, MRCP, Robert McFarland, PhD, MRCP, MRCPCH, Emma L. Blakely, PhD, Langping He, PhD, Roger G. Whittaker, MRCP, Robert W. Taylor, PhD, MRCPath, Patrick F. Chinnery, PhD, FRCP, MRCPath, and Douglass M. Turnbull, MD, PhD, FRCP

Objective: Diverse and variable clinical features, a loose genotype–phenotype relationship, and presentation to different medical specialties have all hindered attempts to gauge the epidemiological impact of mitochondrial DNA (mtDNA) disease. Nevertheless, a clear understanding of its prevalence remains an important goal, particularly about planning appropriate clinical services. Consequently, the aim of this study was to accurately define the prevalence of mtDNA disease (primary mutation occurs in mtDNA) in the working-age population of the North East of England.

Methods: Adults with suspected mitochondrial disease in the North East of England were referred to a single neurology center for investigation from 1990 to 2004. Those with pathogenic mtDNA mutations were identified and pedigree analysis performed. For the midyear period of 2001, we calculated the minimum point prevalence of mtDNA disease for adults of working age (>16 and <60/65 years for female/male patients, respectively).

Results: In this population, we found that 9.2 in 100,000 people have clinically manifest mtDNA disease, making this one of the commonest inherited neuromuscular disorders. In addition, a further 16.5 in 100,000 children and adults younger than retirement age are at risk for development of mtDNA disease.

Interpretation: Through detailed pedigree analysis and active family tracing, we have been able to provide revised minimum prevalence figures for mtDNA disease. These estimates confirm that mtDNA disease is a common cause of chronic morbidity and is more prevalent than has been previously appreciated.

Ann Neurol 2008;63:35–39

AUTISM AND MITOCHONDRIAL DISEASE

Richard H. Haas[1,2]*

[1]Department of Neurosciences, UCSD Mitochondrial and Metabolic Disease Center, University of California San Diego, La Jolla, California

[2]Department of Pediatrics, UCSD Mitochondrial and Metabolic Disease Center, University of California San Diego, La Jolla, California

Autism spectrum disorder (ASD) as defined by the revised Diagnostic and Statistical Manual of Mental Disorders: DSM IVTR criteria (American Psychiatric Association [2000] Washington, DC: American Psychiatric Publishing) as impairment before the age of 3 in language development and socialization with the development of repetitive behaviors, appears to be increased in incidence and prevalence. Similarly, mitochondrial disorders are increasingly recognized. Although overlap between these disorders is to be expected, accumulating clinical, genetic, and biochemical evidence suggests that mitochondrial dysfunction in ASD is more commonly seen than expected. Some patients with ASD phenotypes clearly have genetic-based primary mitochondrial disease. This review will examine the data linking autism and mitochondria.
Dev Disabil Res Rev 2010;16:144–153.

dysfunction in the etiology of ASD, however, may be much more important than this Venn diagram would suggest.

Neurodegeneration in primary mitochondrial disease patients is frequently precipitated by infection, postulated to be mediated by metabolic decompensation and cytokine toxicity. More recently, autistic regression with resulting ASD in children who were thought to be previously normal has been reported following fever associated with infection or immunizations. Some of these children are subsequently recognized to have primary mitochondrial disease—"Mitochondrial Autism," a term suggested by Weissman et al. [2008].
